[Patch Management Statistics](#)

Deployment and Reporting

With patch testing completed and all problems resolved, your patch management tool should make it very easy to deploy your latest patch baseline across all target systems – without disrupting end users.

When patches are deployed during the business day they can negatively impact end users. For example, if reboots are required there may be a significant loss of productivity. A good patch management tool should have the ability to deploy patches overnight. It should utilize technologies like Wake-On-LAN to deploy required patches even when endpoints are asleep. It should also handle reboots and return endpoints back to their shutdown or sleep mode.

The final but critical step in your monthly patch process should be to report your success. It is important that management see the patch coverage for the entire environment. A leading patch management tool should allow you to easily create automated reports that quickly convey patch status.

It should support bright colors, timeline views and a security risk assessment to accurately gauge your company's existing vulnerability exposure. It doesn't hurt to share statistics about the success rate of your patches. The work you've put in to patch testing should be recognized.
